Deep learning has recently become a viable approach for classifying Alzheimer's disease (AD) in medical imaging. However, existing models struggle to efficiently extract features from medical images and may squander additional information resources for illness classification. To address these issues, a deep three-dimensional convolutional neural network incorporating multi-task learning and attention mechanisms is proposed. An upgraded primary C3D network is utilised to create rougher low-level feature maps. It introduces a new convolution block that focuses on the structural aspects of the magnetic resonance imaging image and another block that extracts attention weights unique to certain pixel positions in the feature map and multiplies them with the feature map output. Then, several fully connected layers are used to achieve multi-task learning, generating three outputs, including the primary classification task. The other two outputs employ backpropagation during training to improve the primary classification job. Experimental findings show that the authors' proposed method outperforms current approaches for classifying AD, achieving enhanced classification accuracy and other indicators on the Alzheimer's disease Neuroimaging Initiative dataset. The authors demonstrate promise for future disease classification studies. © 2024 The Authors. <p>Hide abstract <span>▲</span> <a href="#">View at Publisher</a> Related documents</p> <p>This work presents a holistic framework for automating automated guided vehicles (AGVs) in industrial settings by using well-positioned sensors and sophisticated machine learning models. The AGV is put through rigorous testing along a variety of industrial pathways. It is outfitted with sensors such as wheel encoders, proximity sensors, ultrasonic sensors, and LIDAR. Microcontrollers in the high-speed electronic system enable real-time data processing and decision-making based on sensor inputs. For the purpose of anticipating impediments and maximising AGV routes, machine learning models such as decision trees (DT), artificial neural networks (ANN), support vector machines (SVM), and random forests (RF) are developed and assessed. Experiments showing accuracy, F1 score, precision, and recall show how well the integrated system is. The AGV is a prime example of effective route planning, obstacle avoidance, and navigation in busy industrial settings.</p>
